

Appium uses Apple's XCUI Test API for app testing purposes. XCUI Test is an automation framework that combines with Apple XCode. The framework works on the UI elements holistically to give a good output.

Below are the steps that look into the working details of Appium for iOS devices:

- Appium's Apple Client connects with the Appium Centralised Server using the JSON Wire Protocol.
- The server initiates an automation process instantly. The Appium Server looks into the capabilities and requirements of the client. Upon checking out the credentials, the client is connected to the XCUI Test that takes them further into the testing process.
- The XCUI Test framework takes over the task of working on the App testing process by connecting with bootstrap.jar. Client operations are performed by bootstrap.jar.
- Bootstrap.jar sends the appropriate command over to the Apple Client using the XCUI Test framework.
- Upon doing this, the developer shall make the appropriate changes to the code and optimise the App accordingly for its customers.

Appium for iOS

Appium and Selenium

Appium is just an extension of Selenium, but for the genre of mobile applications. While Selenium is an automated web application framework, Appium is much more than just a mobile application testing framework. Appium caters to the testing of web applications when used on devices and browsers. Appium is a hybrid framework that can be used across all kinds of the framework. Appium's framework does link itself with Selenium as
