

both used the JSON Wire Protocol. Appium interacts with its Android and iOS clients using the basic Selenium WebDriver.

As far as its architecture is concerned, both Appium and Selenium are based on an HTTP-based server written in Node.js. This server handles the sessions of both the testing platforms. There is not much of a difference between Appium and Selenium. They are an extension of each other, while the only difference being their functional area.

What makes Appium a favourite among testing frameworks?

Time and again, Appium has proved itself as one of the preferred frameworks for mobile app testing. The flexible automated framework allows testing for Native, Hybrid, and Mobile Web Apps for Android, iOS, and Windows network in a dynamic manner.

It has established as the first choice app testing framework for developers due to the below-mentioned features:

- Appium works on a server that runs in the background and provides minimum interruptions in the App Development process. This allows for a smooth testing process for the developers.
- Since Appium is an open-source testing framework providing a wide range of flexible options, it can be synchronised with TestNG. TestNG is a framework that provides a plethora of options to developers. It allows them to explore the options to make use of any novelty to make their process smooth.
- Appium leaves the control of the back-end APIs and databases at the hands of the developers. It allows them to control the processes in a much better manner. This feature leads to immediate identification of faults and their solution.
- Appium comes with the UI Automator. It allows Appium to produce a detailed information log to inculcate a reporting structure to make analysis better. It allows for better debugging.
- Appium gives developers to write their codes in any of the preferred languages. It should suit the development process. The language scripts can be written in Java, JavaScript, PHP, Ruby, Python, and C++.
- Appium used the UIAutomator, UIAutomation, or Xcode9 for parallel automation of the testing process. These make the testing process fast and scale up a notch.
- Appium uses standard automation APIs, which prevents developers from modifying or recompiling the App for every platform. This fea-
