

such as Video, Django will now allow the video model to inherit properties from the base model.

Suppose you create a base model,

```
• from django.db import models
• import uuid
• # Create your models here.
• class Content(models.Model):
•     content_id = models.UUIDField(primary_key=True,
default=uuid.uuid4, editable=False)
•     content_slug=models.CharField(max_
length=100,unique=True)
•     content_title=models.CharField(max_length=100)
•     content_subtitle=models.CharField(max_
length=255,null=True, blank=True)
•     content_headline=models.CharField(max_length=100)
•     content_modifieddate = models.DateField()
•     content_createddate = models.DateField()
•     def __str__(self): # __unicode__ on Python 2
•         return self.content_title
•     class Meta:
•         verbose_name = "Content"
•         verbose_name_plural = "Content"
```

Here, the model created is Content with basic properties like ID, title, subtitle, and headline. Django maps the model through appname_content. The content model will inherit from the model.model. Now, if you have a Video model, it will inherit from the Content rather than model.model

```
• from django.db import models
• from contentmanager.models import Content
• import uuid
• # Create your models here.
• class Video(Content):
•     video_id = models.UUIDField(primary_key=True,
default=uuid.uuid4, editable=False)
•     video_link = models.URLField(null=True, blank=True)
•     video_source_guid = models.CharField(max_
length=255,null=True, blank=True)
•     video_embed = models.TextField(null=True,
blank=True)
•     video_copyright = models.TextField(null=True,
blank=True)
```
