

the latest version of Python has been installed on your system before heading to the Django framework.

One question that may arise in your mind is “why is there this dependency on Python?”

As Django is a Python framework, it becomes quite obvious why Python is mandatory before its installation. Most systems have Python installed already, but in case one needs assistance over its installation, please visit <https://www.python.org/downloads/>. The website is updated with the latest release of the official Python versions. The last time we checked, it was Python 3.8.5. You can also check the version through `python --version` command in PowerShell after installing Python and to check the success of the same.

```
Windows PowerShell
Windows PowerShell

Try the new cross-platform PowerShell https://aka.ms/pscore6

PS C:\Users\dumpy> python --version
Python 3.8.5
```

Check the version of Python

Which version of Python is compatible with Django?

The Python version should be installed on the system based on the version of Django that is to be installed. The general suggestion would be to go with the latest versions of Python and Django. With Django versions 3.0 and 3.1, the Python versions to be used are 3.6, 3.7, and 3.8. Generally, these versions support an up-to-date Python version, which includes the initial Django LTS release since the security support ends right after each other's expiry.

For example, Python 3.3 security support updates expired in September 2017, and Django 1.8 security support expired in April 2018. Therefore, Django 1.8 was the last version compatible with Python 3.3 and later versions. The latest updates of any application come with new features, new upgrades and improved user experience.

Set up the database

Django's database functionalities can be used only if there exists a database running on the server. Django facilitates different database servers such as MySQL, Oracle, SQLite, PostgreSQL. SQLite can be used for small projects
