Django projects require a superuser. This user will have authority over each character of Django, so it's crucial to establish this first. While we can have an obvious password in our development environment, it's crucial to have a strong password on production systems.

## What is the Django development environment?

Django makes it very simple and easy to arrange our machines so that we can commence evolving web applications. The development environment is an establishment of Django on our local machine, which we can utilise to develop and sample Django applications before deploying it to a production environment.

The main methods that Django delivers are a bundle of Python scripts for building and functioning with Django projects, along with a thorough development web server that we can use to test local (i.e., on our machines, not an outer webserver) Django web applications on the machine's web browser.

There are other peripheral methods that construct a portion of the development environment, which we won't cover here as the scope is limited. These comprise aspects such as a text editor or IDE for amending code and a source maintenance management tool like Git for safely governing several editions of the code. We have assumed that we already have a text editor installed, such as vs code, sublime and so on.

## Install Django

Installation directions are somewhat varied depending on whether we install a distribution-specific package, the newest official deliverance, or retrieve the latest development version.

### Using pip

This is the suggested method to install Django:

1. Install pip: The easiest way to install pip is to use the standalone pip installer. If the administration has pip previously installed, we might
