

Testing installation

Though the earlier test operates, it is not enough. A better, more unusual test is to generate a skeleton project and understand its workings. To achieve this, first, operate in the command terminal where you want to store the Django apps. Create a folder for the test site and enter it.

```
1 mkdir django_test
2 cd django_test
```

Then, create a new skeleton site of any name that pops in your mind through the Django-admin tool. After generating the site, you can navigate into the folder where you will discover the main script to manage projects, which is called `manage.py`.

```
1 django-admin startproject mytestsite
2 cd mytestsite
```

Now, you can run the development server through the `runserver` command:

```
1 $ python3 manage.py runserver
2 Performing system checks...
3
4 System check identified no issues (0 silenced).
5
6 You have 15 unapplied migration(s). Your project may not work
7 Run 'python manage.py migrate' to apply them.
```

Once the server is working, you can inspect the section by operating the following URL into the local web browser: <http://127.0.0.1:8000/>. The screen in the image on the next page will appear on the browser. Just make sure the screen appears to ensure everything has been done smoothly and accurately.

There you go! Django is working fine if this is what you see on screen. The Django environment is running successfully on the machine. You can start with basic app creations on Django to utilise all the myriad features of Django.
