Passing extra data to the Callback Function

The callback of a request represents a function that can be called upon when the response object of that request gets downloaded. The callback function is also called along with the downloaded response object as the initial argument. For example,

```
• def parse_page1(self, response):
•     return scrapy.Request("http://www.example.com/
some_page.html",
•                               callback=self.parse_page2)
• def parse_page2(self, response):
•     # this would log http://www.example.com/some_
page.html
•     Self.logger.info ("Visited %s", response.url)
```

In a few cases, a user might be willing to pass the arguments to these callback functions so that they can receive the arguments later in the second callback. In the below-mentioned example, you will see how to achieve this objective by using the attribute `as- Request. cb_kwargs`.

```
• def parse (self, response):
•     request = scrapy.Request('http://www.example.com/
index.html',
•                               callback=self.parse_
page2,
•                               cb_kwargs=dict(main_
url=response.url))
•     request.cb_kwargs['foo'] = 'bar' # add more
arguments for the callback
•     yield request
•
• def parse_page2(self, response, main_url, foo):
•     yield dict(
•         main_url=main_url,
•         other_url=response.url,
•         foo=foo,
•     )
```
