

In this chapter, we will cover Django models and admin backend with the steps to build a web application using Django. These are the basic steps:

- Database Setup
- Create a model
- Activate a model
- Create a Poll App
- Django admin

Database setup

The first step is to set up a database. Open `mysite/settings.py`. You will see a python module that has a modular-level variable that represents the Django setting. Here, SQLite is the default configuration, and if you are new, it is the easiest choice to begin with. There's no need to install any additional databases.

But if SQLite is not your option as a database, Then you have to do some additional settings such as adding a user password and a host. For more details, refer to the official document on Django and check out the section specific to databases.

When you are going to edit the `mysite/settings.py`, you can set your Time Zone.

Also, you must check the settings of all the `INSTALLED_APPS`. On top of the file, you will see the name of all activated Django apps in Django instances. These apps are utilised in a number of projects. You can also package and redistribute it for utilisation by others in their projects.

By default, all these apps come with Django. The following apps are contained in the `INSTALLED_APPS`

- `django.contrib.admin` – Related to the admin site, which we will use shortly.
- `django.contrib.auth` – for the authentication system.
- `django.contrib.contenttypes` – content types framework.
- `django.contrib.sessions` – session framework.
- `django.contrib.messages` – messaging framework.
- `django.contrib.staticfiles` – manage static files with this framework.

All these applications are included for better convenience and use cases. Some of the above-mentioned applications use at least one database table. In order to do this, we have to create tables. To create tables, run the following command (run as per your operating system):
