

Let's Create Our Poll App

After defining the activation of models, now it's time to create our Poll App using the Django framework. Here, we are creating a basic Web-based Poll application. It will contain two parts:

1. One public site for voting & people viewing the polls
2. One admin site to perform tasks like adding, changing and deleting of the polls

For the Application creation, we have to do these three things first.

1. Install Django

Let's assume that we already have Django installed. To check whether Django is properly installed and to know which version is running; follow below-displayed command in the shell prompt (run as per your operating system) :

In case the Django is not installed then you must see the version of its installation. But in case it is not installed then you see an error similar to “No module named Django”.

This Chapter is particularly written for Django 3.1, that supports Python 3.6 and versions later than that. If your Django version, not match, then try switching to another version of Django else you can also perform the newest version update on Django. Also, you need to check the Python version because in case you are using an old version of the Python, you may check “What Python version can I use with Django?” for compatible versioning with the Django on the official website.

2. Create A Project

We need to create a Project after successful installation. Some initial setups need to be taken care of for the first time. So, you have to auto-generate a few of the code/s that do establishments for the Django project.
