

Further, point this root 'URLconf' at 'polls.urls' module. Then in the `mysite/urls.py`, just add the import for 'django.urls.include'. After that, insert function of an `include()` into the 'urlpatterns' lists, so now you have the following code:

```
mysite/urls.py

from django.contrib import admin
from django.urls import include, path

urlpatterns = [
    path('polls/', include('polls.urls')),
    path('admin/', admin.site.urls),
]
```

This `include()` function will allow the referencing of other 'URLconfs'. So, whenever the Django meets this `include()` function, it fetches and removes the part of the URL that matches up with that point. Afterwards, send the remains of the strings for further processing work to all the included 'URLconf'.

The concern here behind the `include()` function is to make it an easy URL for plug-and-play. With this, we have got wired a lucrative 'index view' into the 'URLconf'. Now, let us verify whether it is working properly using the following command (run as per your operating system):

```
$ python manage.py runserver
```

```
...> py manage.py runserver
```

From your browser go to – <http://localhost:8000/polls/> and there you will see this text- “Hello, world!”, the same that we have defined in the 'index view'.
