

applications. With a framework, it is possible to provide generic functionality to an application and change the additional user-written code.

All these frameworks follow a specific architecture in the way they are executed. There are primarily two software architectures that are discussed with regard to frameworks: MVC (Model View Controller) and MVT or MTV (Model View Template).

MVC Architecture

MVC is a software design pattern consisting of the model, the view, and the controller, where the model signifies the data to be handled, the view points to the user interface and the controller directs the processes required to handle input. The MVC model blends well with object-oriented programming, where the different models, views and controllers are treated as objects and can be reused in an application.

The following is a detailed description of each part of the MVC model:

1. Model

A model is the data used in a program and can be in the form of a database, file, or a simple object depending on the application to be designed.

2. View

A view is how objects are displayed in an application. It includes the object the user can see on the UI.

3. Controller

A controller, as the name suggests, controls the model and the view by accepting input and executing an update.

Drawbacks of the MVC architecture

Although it being a versatile software pattern, the MVC architecture has the following drawbacks:
