

3) Views

Views in MVT handle all the business logic in the application and acts as a link between the Models and the Templates. It retrieves data from the database upon user requests and outputs the template with retrieved data.

Difference between MVC and MVT

The controller in the MVC handles the entire logic behind an application. It works upon the user request based on Http and sends an appropriate response, whereas there is no separate controller in the MVT architecture, and everything is handled with the Model – View – Template architecture itself.

This is what makes Django unique. It implements the MVT architecture, which is comparatively faster, robust, and more secure. It prefers to use logic implementation in its web app and handles all the controller parts by itself.

This is a simple step by step explanation of the Django MVT control flow:

- i. A user sends a URL request to the Django database.
- ii. The Django framework searches for the appropriate URL resource.
- iii. If a view associated with the URL is found, Django calls that view.
- iv. The view will interact with the Model and retrieve the data from the database.
- v. Finally, the view extracts an appropriate template along with the retrieved data for the user.

Understanding Django Views

Views in Django are Python functions or classes where the logic of an
