

Template tags, help to transfer Python-related objects into HTML for building dynamic websites.

They are declared in a template as {% <tag name> %}. Tags are used to perform several functions such as displaying or modifying text and controlling the flow by adding loops or if statements. In Django, there are over twelve in-built tags, but it also offers the flexibility to write your tag or use third-party tags when needed during programming.

Template Variables

Django templates provide the capability to display variables. Templates are rendered by a view. You can create Python variables in a View and display them. Variables are displayed using the syntax {{<variable name>}}. An instance of using variables is fetching information from a database. This information can be in the form of contents of a blog post displayed on a web page.

Base Templates

Base templates are the first step of creating templates for a web application. It works like a frame for all pages in the application. It projects common HTML elements such as the navigation bar, the site footer, and provides a standard body layout for all the web application pages. With the base template, the duplication of an HTML code can be avoided.

Create the Project Base Template

The first step while creating templates for a project is to create the base template. The base template acts as the frame for all the pages in an application. It defines the navigation bar at the top, the footer, and provides a body frame for any page to be customised. By using the base template, the standard look and feel can be devised without duplicating the HTML code.

Program for Base Template

Step 1: Create the Base.html File

Create the base.html file in the directory of the template.

- i. Navigate to the templates directory
- ii. Create a file in this directory called base.html and open it for editing in your IDE

Step 2: Write the code for Base.html file

The base.html file has the most number of lines of code in a project.
