

Django, certainly unchained

One of the most loved frameworks, as per StackOverflow's 2019 Developer Survey, Django is a Python framework that makes developers' jobs much easier. There are several reasons that contribute towards Django being the mass favourite, chief among which happens to be the beginner-friendliness of the framework. Even the documentation is outright simple with focus on getting the learner through the entire framework one step at a time through a sample project. Developers also prefer to get all the documentation for the individual methods and you'll find that as well. So it satiates the needs of both beginners and advanced students.

Then there's the fact that this happens to be a Python framework, one of the most popular and flexible programming languages out there. Django simplifies the website creation process like no other. A lot of the aspects that generally require multiple stakeholders are implemented by Django, so in a way, folks who know Django are perceived to be more valuable to a company since the work they do frees up a lot of resources which can be put to use elsewhere in the company.

Another key aspect in Django's favour is how you can implement security through it. Since Django is used in a lot of big projects, the security features that are often required for large projects have been baked into the framework. Common security mistakes that open your site up to cross-site scripting, cross-site request forgery and SQL injection are all handled by Django by default. It even provides for developers to detect click-jacking and implements methods to handle referrer and session security quite well.
