

There is a feature that template offers with which you can import or include other templates. This feature is useful for building reusable templates.

With Django, the settings file is updated with the path of a templates directory which will contain all the templates used in a certain project.

Templates and views work together as templates are delivered by views.

## The Home Page Template Program

This section focuses on creating the home page template, which extends the base.html file with the following steps.

### Step 1: Creating the Marketing Template Directory

It's important to organise the template files in the same hierarchy as Django apps. Here, the first step is to create a folder named 'marketing' in the templates directory.

- i. Navigate to the templates directory
- ii. Create a new folder in the directory with the name 'marketing/'

The hierarchy followed looks like this:

```
crmeasy/
|---crmapp/
|---templates/
|---marketing/
```

### Step 2: Create the Home.html File

For creating the home.html file, follow these steps:

- i. Navigate to the marketing templates with the code `../crmeasy/crmapp/templates/marketing`
- ii. Create a file in the folder home.html and open it for editing.

### Step 3: Write the code for the Home.html File

The code for this section is too long, hence we will write it in blocks followed by a full version of the file at the end.

#### i. Extending the Base.html File

The first part deals with extending the base.html file and setting the value of the blocks.

- `{% extends 'base.html' %}`
- `{% block title %}Home{% endblock title %}`
- `{% block nav-style %}mkt-nav{% endblock nav-style %}`
