

```

•         {% csrf_token %}
•         {{ form.as_p }}
•         <button type="submit" class="save btn btn-
default">Save</button>
• </form>
• </body>

```

We can now create the form and define the input fields for the form, the code for which is given below.

```

• from django import forms
• class StudentForm(forms.Form):
•     firstname = forms.CharField(label="Enter first
name",max_length=50)
•     lastname = forms.CharField(label="Enter last name",
max_length = 10)
•     email     = forms.EmailField(label="Enter Email")
•     file      = forms.FileField() # for creating file input

```

We can now create the view for the form. We would be discussing the concept of views in great detail at a later stage, but as of now, views can be understood as the page that is displayed to the user. This is a pivotal part of the Django framework.

```

• from django.shortcuts import render
• from django.http import HttpResponse
• from myapp.functions.functions import handle_uploaded_
file
• from myapp.form import StudentForm
• def index(request):
•     if request.method == 'POST':
•         student = StudentForm(request.POST, request.FILES)
•         if student.is_valid():
•             handle_uploaded_file(request.FILES['file'])
•             return HttpResponse("File uploaded success-
fully")
•     else:
•         student = StudentForm()
•         return render(request,"index.
html",{ 'form':student})

```

Now mention the path where you specify the URL with the following code:
