Let us try and briefly understand both types of views.

Function-Based Views

The Function-Based Views in Django are views that are written by defining a function in Python, which can receive the [HTTPRequest](#) Object, and give an [HTTPResponse](#) Object as an output. The Function-Based Views are used to implement the logics for Create, Retrieve, Update, and Delete (CRUD) views.

Class-Based Views

The Class-Based views are views that allow you to implement the view architecture as objects rather than functions. They might not be able to replace the Function-Based views but have certain advantages when compared with them.

Let us have a look at the advantages that Class-Based views have to offer.

- The Code organisations related to the HTTP methods can be addressed as separate methods instead of the traditional conditional branching.
- Object-Oriented techniques such as Multiple Inheritance can allow the reusability of code.

The Class-Based views can be managed efficiently and are simpler too. The Object-Oriented Programming Approach comes into the picture with the Class-Based Views. That helps us to convert the Function-Based Views to Class-Based Views with just a few lines of code. Now, We proceed to learn about a special type of Class-Based View, which is called the Generic View.
