

Generic View

Coding a web application can be a monotonous task, where certain parts of code have to be repeated again and again. The Model and Template layers have taken care of the problem of redundancy. However, this problem persists at the View level too.

The Generic Views help you avoid redundant coding at the view level and allow you to insert common views without writing the code. They identify the most-used idioms and patterns and abstract them for you to call whenever you require.

The Generic Views help you save a lot of time in development. However, they have their limitations too. There comes a time when developers struggle to use Generic Views to handle a wide range of situations. The Generic Views do not allow you to implement a subclass of the view. So, you would have to go back to either Class-Based Views or Function-Based views.
