

IFS

The new IFS function presents itself as a welcome alternative to typing tiring complicated and monotonous nested IF functions. Many users often require to draw a correlation between various slabs and segments of their database to reach a conclusion. To achieve this objective, they make use of the IF function, albeit in a nested construct. Although this system is fairly effective and reliable, it proves to be a major hindrance in the way of time consumption when voluminous databases are considered. Excel 2019's IFS function announces itself as the perfect solution to this dilemma. Using the IFS function, an user can also specify the order or the specific chronology in which they want their conditions tested within the database. In the event that the condition is passed, the IFS function returns the result. In the case that no stipulated conditions are achieved, the users can define a "catch all" statement as an else clause. Users need to keep in mind that to specify a default result, they need to enter TRUE for their final logical test argument. In that case, if none of the other conditions are met the corresponding value will thus be returned.

MAXIFS

The MAXIFS serves the function of returning the number that has the largest value in a given range. It does not matter if this value meets a solitary criterion or a set of different criteria simultaneously. An important note to keep in mind while using the MAXIFS function is that the size and shape of the argument that specifies the actual range of cells in which the maximum will be determined and the argument that specifies additional ranges and their associated criteria should be the same. Failure to do so will result in the functions returning the #VALUE! error.

MINIFS

The Excel 2019 MINIFS function is quite similar to that of the MAXIFS function. The only difference lies in the fact that whereas MAXIFS returns the largest number in a defined range, MINIFS exists to return the smallest number in that particular and specific range. Similar to MAXIFS, MINIFS also does not concern itself with its returning value meeting a single criterion or various criteria simultaneously. The stipulation regarding the shape and size of the argument that specifies the actual range of cells in which the maximum will be determined and the argument that specifies additional ranges and their associated criteria being the same, holds true in the case of MINIFS as well.
