

Modifying custom measures

By utilising the PivotTable fields list, you can now implement these functions directly from there. As a result a user is able to save a lot of time whenever they have a need for including additional calculations for their analysis.

Auto time grouping

The automatic time grouping feature helps you make the best possible use of time-related fields such as year, quarter and month in your PivotTable, by facilitating the auto-detecting of these fields and subsequently grouping them on the user's behalf.

PivotChart buttons

These buttons let you to zoom in and out through hierarchical structures and other groupings of time that exist in the confines of your data.

PivotTable Search

This field list in the PivotTable helps you effectively navigate to the fields of your choice and other such important fields which are present across your complete data set.

Smart rename

The smart rename feature allows you to rename any and all tables and columns which are present in the data models of a particular workbook. For every change that is made, Excel updates all relevant tables as well as calculations through your workbook, including but not limited to work-sheets or DAX formulas.

Usability improvements

Courtesy of these upgrades, now delayed updating lets users carry out several modifications in Power Pivot with no need to wait for each change to be conveyed through the workbook. Once the window closes, all the changes are carried out at once.

Slicer

By using a touch device, you can now choose more than one item in an Excel slicer. Earlier, users could only select a single item at any given instance of time in a Slicer using the same touch input.
