

have to apply Center Markers to every element and form Magnet Targets to set the positions where the elements that are displaced must go back.

When you have Magnet Targets for every element, you can design a node-based copy of the character in the SMR panel and tag all the symbols with SMR metadata or SMR info.

It makes the rig informed of all the elements and their hierarchy (parent and children).

SMR helps you to make responsive chain selections in the hierarchy with Smart Transform, interactive posing with the help of Kineflex and assembling parts with the help of Smart Magnet Joint.

Features of Rigging

- **Inverse Kinematics**

It is used for living organism models. With the help of IK, you can recreate natural body movements in the way living organisms move. This feature is used to move the object by itself.

Animators use this feature when their character interacts with other objects. You can use it too if you want your character to interact with other characters or objects like a book or a house. In IK, a child joint manages the parent joint.

Another example of Inverse Kinematics is if your character is picking up an object or fighting, you will use this feature for the animation.

- **Forward Kinematics**

Forward Kinematics also works with Parent and Child joints, where the Child joint is controlled by the Parent joint.

The lines are connected to create movement. The Parent controls the Child here. It happens when your character – the living animation comes in contact with a non-living or still objects.

Let's take an example of a bird that is animated to appear to fly naturally, and the movement of the wind is replicated.

- **Control Curves**

During the rigging process, you might overlap joints. So, it becomes tough for you to manage these joints. You can use control curves to work on these joints. Thus, with the help of the control curve feature, you can modify, move or update a joint. It eases the process of animation.
