

choose the “Properties” option. In the layer properties, you can set the layer height to 100 percent or 300 percent. Press Enter after you’ve done this.

Working with audio compression options

To start working with the audio compression options, you need to import an audio file inside Adobe Animate. Try to have a small-sized audio file when you bring an mp3 file heavy on space. Your audience may need to wait sometime before they access the content.

Head over to the library to work with the audio, and select the audio clip you want to edit. Right-click and go to properties, and by default, you’ll have the file extension you have imported.

Perform one of the following actions to compress a sound:

1. Double click the sound icon present in the library panel.
2. Right-click on Windows or Control-click on Mac and select properties.
3. Select a sound in the Library and click on properties present at the bottom of the Library.
4. To compress, select ADPCM, mp3, Default, or Raw. The default compression uses global compression settings present in the publish settings box when you export it to the SWF format. In the case of the Default option, there are no additional export settings present.
5. Set the export settings and click test to play the sound. Adjust the export settings in case necessary until the desired quality is achieved.

Work with the right sound
