

Animation happens when your digitally created characters move and walk, adding tons of life and personality to their existence. Thankfully, Adobe Animate comes equipped with multiple features and techniques to help get the desired outcome effectively. Use this interesting tool to bring life to your animated characters. Since there are lots of complexities involved and much to learn before one can master the art, this chapter is dedicated to help you learn the steps to create real-life walk cycles, adjust leg lengths, and address every part of the character well so that the character walks without slipping or looking awkward.

Here, we will learn how to fine-tune their walk so that each step in the animated stride is well coordinated. In the end, you will have the animated characters walking with grace, just like they would in the physical world.

Starting with the character de-grouping body parts

The purpose of adding a walk feature to your character in an animated movie is to allow them to move from one place to another, just like real characters in a movie.

The first step in the process is to have your physical model, photographed in real life in a green screen set. In case you wish to showcase your creativity, you can use a hand-drawn animated character and use the steps mentioned

Character's body part groups
