

be used to get desirable results. Conventional animation background has an old-fashioned way for the developers to create a running cycle, i.e. frame by frame, but Animate gives you access to the shape tweens and motion to develop sleek animation clips quickly.

If you have a simple objective of creating fades, just moving the object from one instance to another, or transforming the rotation and size, you can use the motion tweens. Animate is loaded with various tools and features to develop professional-quality moving animations. You can easily create keyframes, timelines, and layers of multiple actions, and put it all together to create the moving animation. For instance, Animate has various elements like Tweens that are easy to move from one point to another. The developers can easily save them as presets and then reuse or mix match it with already existing components for upcoming projects.

How to develop a running cycle with Adobe Animate

Many developers hesitate creating animation running cycles because many events might be happening simultaneously, and it can be overwhelming to incorporate each one of them carefully. With Adobe Animate, you can easily break down the process in an easy series of steps that can simplify the process of creating a running cycle. In general, the running cycle is described in four distinct stages, which are –

- Contact
- Recoil
- Passing
- High point

The aforementioned pose and some of the in-between drawings comprise a complete running cycle. The most important pose out of the four is the contact pose, and as soon as you have created it, 70% of your run animation is done. Any mistake or error in the contact pose can complicate the whole project for the developer. Hence, pay attention to the contact force to save yourself a whole world of troubles. Let us explore each of these poses in brief.

1. Contact pose – In contact pose, you have to pay attention to the feet as it is the extension in the whole cycle. This pose alone makes the most important part in the sequence, and you can easily plan the whole animation just by carefully laying the contact pose. Some animators believe that recoil or highpoints are an important pose where the head is placed at its highest and lowest position. However, this is not entirely true because contact pose
