

is the fundamental component of a running cycle. You are doomed if you have not started this cycle with the feet pose.

- When the right foot is forward, place the item back, and vice versa (counterpose)
- You have to prepare the character forward and lean it into the run

2. Recoil pose – Recoil pose is the second most important post in the running animation, and in this frame, the character can easily impact the entire background. In the running cycle, the recoil pose is the lowest point. You have to stretch the character's arms far from the body hitting the ground, where the front foot is in contact with the ground and the rear foot is lifted up. Leading foot, it is beneath the body and supporting body weight above it.

(Many animators create record poses where foot doesn't underlay the body but a few inches ahead. Make sure to avoid this.)

3. Passing – At this stage, you have to start the running animation by drawing the ground or floor guidelines. As with the run cycle, you have to animate the guideline for both feet where the footfalls have to be consistent. When a character runs, the head is usually the highest component in the passing position of legs. With this instance, the character itself catches one leg, and then the next one goes into the transition of passing position. Do not get afraid to draw the guidelines through your running character as it will help you determine how the back foot will be anchored into the character body.

4. High point – As the name suggests it is the highest point in the cycle where the character of the running body is stretched to its fullest as soon as a character lifts the leading leg forward. The heel of the leading or trailing foot is the starting of leaving the ground.

These are the four most crucial poses of creating a running animation with Adobe Animate. If you can potentially wrap your head around each one of them, you will have a clear cut understanding of finishing a satisfactory run cycle.

Tweening for a smooth animation

Before starting working on the motion tween, it is important to understand the use of editing and timeline properties. You can also edit individual properties on stage using motion editor.

Tween refers to the in-between concept in which developers streamline one concept from one instance to another. Animate has everything that you would require to create motion between the keyframes and have
