

We can see there are sections called scenes, sources, Audio mixer, Scene transitions, and Controls. Under controls sections, click settings.

General :

In the general section, choose dark as the default theme. Other sections do not need Changes.

Streaming :

In this section, you can choose your service in which you are going live. Select one of the services included in the dropdown. Pre-defined live streaming profiles are present for YouTube, Twitch, Facebook, and Twitter. Obtain the stream key from your login credentials and feed it here.

Output:

At the output tab, choose the advanced section. It is the output mode that is going to determine the quality of your live streaming and your PC performance. Advanced more provides more options to configure the recording and streaming of the video. It is recommended to not change from simple mode, unless you need it.

Bitrate for video and audio can be configured in the output mode as follows. You can always go higher if your streams are stable.

- Video bitrate: 6500 kbps.
- Audio Bitrate: 128.

The maximum video bitrate for live streaming on certain platforms is limited. If you set more than that, then the platform will not accept your stream. These guidelines change every now and then so keep checking the help pages of the platform to know if they've increased the ingest quality.

Audio:

It is based on the number of audio sources that are used in live streaming. You can pull in multiple audio sources and layer them in different channels. You can also change the sampling rate, and select the number of Desktop audio devices per channel. Ideally, for recording videos and streaming at the same time, try to keep the audio sources on different channel. So that when you are editing your videos for highlights, you can disable unwanted audio channels. Also, configure hotkeys for switching between push-to-mute and push-to-talk as per your preferences. You can also do the same under the hotkeys tab in the settings page.
