

locally installed packages start after this.

Shutting down your FreeBSD system

As you finish your work, you can perform a controlled shutdown, using `shutdown`. Here, `init` tries to run the relevant script `/etc/rc.shutdown`. It sends a TERM signal to all the processes.

If some process doesn't terminate in time, `init` subsequently sends a KILL signal. If a FreeBSD machine is on architecture or system supporting power management, you can use `shutdown -p now` to power off the system right away. Ensure you are root or a member of 'operator' to run `shutdown`. You can also use `halt` and `reboot` to reboot the system. Again, using `shutdown -r now` is another option to reboot. **d**

The right ways to shutdown FreeBSD System
