

ensuring the uninstallation of malicious tools, and checking binaries' integrity. In essence, one needs to be mindful of all the possible threats and insecurities to chalk out an effective security plan of action to defend their system in the best possible manner. In the realm of computer security, the term "threat" encompasses a broad terminology.

The scope of it is not just confined to remote attackers who seek to hack into a system from a remote location illegally. It also includes malicious software, natural disasters, disgruntled employees, security vulnerabilities, unauthorised network devices, and competing corporations. Besides break-ins by remote attackers, networks and systems can also be accessed illegally or without permission via accident, corporate espionage, and sometimes through former employees. Thus, as a user, it is vital to always remain a step ahead of your rivals and attackers by preparing and establishing strategies that can take care of all unexpected security breaches and subsequently report them to the security team in charge. Consequently, as an administrator, it serves you well to be aware of all the threats so that you can equip your system with the suitable tools to dilute them.

Before you implement security in systems, it is advisable that you first start securing and protecting the necessary accounts and the system configuration. Once that is sealed, you may go ahead with booking the network layer to remain aligned with the system policy and the organisation's security procedures and protocols in consideration. Currently, many organisations out there already have security policies in place that are inclusive of the configuration of all those technology devices operating under its wing. The security configuration of all such gadgets, including workstations, mobile devices, desktops, production servers, development servers, and phones, is covered under this policy's blanket. In other cases, there exist standard operating procedures (SOPs) in place that attempt to cover all of these configurations. Usually, the security team in charge can consult and guide you on all matters revolving around these SOPs.

Tools used

Some specific tools that one can use while implementing a security policy on a FreeBSD system are mentioned below.

- **Preventing Logins:** Carrying out an audit of your accounts is generally considered a good starting point towards securing your system in the longer run. Ensure that the 'root' directory is protected with a strong password and that no other entity knows the said password.
