Backup basics

Implementing a backup plan is crucial to recover the data from various issues such as accidentally deleting a file, disk failure, complete machine destruction, random file corruption, etc. The type and schedule of the backups can differ depending upon the factors such as the significance of the data, the granularity for file restoring, acceptable downtime amount, etc. Some important backup tips are:

- Archive the whole system, and backup to permanent and external media. This offers protection against the issues mentioned above. However, it is inconvenient to restore from such data, especially for non-privileged users.
- File system snapshots that are used for storing the previous version files or deleted files. Restoring these is easier.
- Copies of the disks or file systems that are synchronised with the systems off the network using `net/rsync`.
- Software or hardware RAID that minimises downtime in case there is disc failure.
