File backup

```
# /sbin/dump -0uan -f - /usr | gzip -2 | ssh -c blowfish \
    targetuser@targetmachine.example.com dd of=/mybig-
files/dump-usr-l0.gz
```

Directory backups

Multiple inbuilt utilities are accessible for backing up and restoring the files and directories as required. The ideal choice for making the essential files and directories is **tar**. This component dates back to version 6 and assumes a recursive backup to the local device by default. Switches can also be used instead of specifying the name of any backup file. There is an example that developed a compressed backup file of the current directory and saved it to the command `/tmp/mybackup.tgz`. while creating a backup file ensures that the backup is not saved in the same directory that has already been backed up. To back up the current directory with **tar**, use:

- `# tar czvf /tmp/mybackup.tgz`

To restore the entire backup into the directory, try to `cd` into the directory to restore the file and specify the backup name. Keep in mind that this can overwrite the latest version of the files in the restore directory. You can restore the files to a temporary directory or specify the filename within the backup for restoring. To restore the current directory with **tar**:

- `# tar xzvf /tmp/mybackup.tgz`

There are various switches available for data make up that are described in **tar**. This component supports using the exclude patterns for specifying the files that cannot be included while backing out the specific directory
