

Apply free security patches

In case of any application of kernel patches, the system can be rebooted using the patched kernel. A patch has been applied to run the binaries, the applications that have been affected require restarting to use the patched version.

Note: It is a prudent approach to keep a copy of the Generic kernel in `/boot/GENERIC`. It is beneficial in diagnosing various problems via performing version upgrades.

You can configure the system to automatically check updates via adding it to `/etc/crontab`:

```
-----
@daily root freebsd-update cron
-----
```

Where any existing patches are present, the new updates are downloaded but aren't applied. In such cases, the patches can be reviewed manually and be installed by the root user.

To revert any changes made, use the following:

```
-----
# freebsd-update rollbackUninstalling updates... done.
-----
```
