

FreeBSD Partitioning Choices

you have a choice among `FreeBSD-boot`, `FreeBSD-ufs`, `FreeBSD-zfs`, and `FreeBSD-swap`.

- **Shell:** Shell mode partitioning is typically a method for advanced users. In this, you can choose the type and the size of the partition, populate `fstab` and mount file systems one at a time.
- **Auto (ZFS):** The ZFS Partitioning Menu gives you many options and flexibility while partitioning your drive. You select the ZFS pool type and then the disk you wish to partition. Now, your disk is analyzed, and you assign a name to your zpool. Now, choose the swap amount and enter a disk encryption password to encrypt the disk.

Distribution files

The time it takes for FreeBSD to install depends upon several different factors. These include the media that the installation is taking place from, your computer's speed, and whether a network connection is being used. The first step on the part of the installer is to format the disks that have been selected for installation. It then initialises the partitions that have to be created. If a network connection is being used, it also needs to download updated installation files from the internet.

The checksums of the distribution files are now verified. This is done to ensure that the download process has not corrupted the installation files or there hasn't been an error in reading them. Once this verification has been carried out, these files are extracted to the disk in which installation has to take place.
