- 3. The Superuser Account:** Usually known as the 'root,' the superuser account is typically used to exercise control over the system without being subject to any limitations concerning privileges. Hence, one should not use it for executing tasks such as programming, sending and receiving mails, and the like that are carried out daily, to avoid general exploitation of the system. Since the superuser account operates without any restrictions, care must be taken to avoid account misuse. Failure to do so might result in devastating consequences. Hence, users are encouraged to access the superuser account only in cases where they need to execute commands that require extra privilege. Other than that, they are strongly recommended to access the system as an ordinary user account if they wish to avoid causing any unprecedented damage to the operating system. Any commands issued as a superuser account must be thoroughly scrutinized for errors, as even a minor lapse such as a missing character or an extra space can lead to irreparable and immeasurable data loss.

Commands for managing accounts

To manage the various user accounts, FreeBSD offers a host of different commands. They have been listed below for the reference of the reader.

- **adduser:** This command-line application serves the purpose of adding new users to the system.
- **rmuser:** This command-line application serves to remove a user from the system completely.
- **chpass:** This is a flexible tool that is generally invoked for effecting changes on the user database information such as their default shell and other personal information.
- **passwd:** This command-line tool is used to alter and modify user passwords.
- **pw:** This is a flexible and powerful tool that serves the purpose of creating, modifying, removing, and displaying users and groups. Its highly potent set of command-line options make it fit for application in shell scripts.
