Disk organisation

The filename is the perhaps most fundamental unit of organisation utilised by a FreeBSD system to locate its files. Filenames in FreeBSD are case-sensitive. Additionally, FreeBSD does not take extensions into account to determine whether a file is a program, document, or some other form of data altogether. Files are organised within a directory in this environment. A directory may either have no files or have hundreds of files in its possession. Further, a directory is also allowed to maintain other directories and give rise to an organisational hierarchy in the process. These files and directories are referenced by a name and a forward slash as postfix is attached.

Shells and text editors

A shell provides the users with a command-line interface for communicating with the operating system in a FreeBSD system. Post receiving commands from the input channel, a shell concerns itself with executing them. Many shells offer inbuilt functions that aid day-to-day tasks such as file globbing, command macros, file management, command-line editing, as well as configuring environment variables. On the other hand, text editors facilitate convenient FreeBSD configuration for the majority of it is carried out by editing text files. FreeBSD offers a host of powerful text editors that inherently belong to its base system.

Conclusion

Although learning the basics of a FreeBSD system isn't an overwhelming affair, it can certainly tend to be time-consuming owing to the vast number of features and commands it entails. Hence, users are advised to be extremely careful while picking up the various attributes of this environment to familiarise themselves with it in the correct vein eventually. **d**
