

- **Make fails:** The `make` directive usually fails when there's some error in the kernel configuration file that is not severe enough for `config` to intercept.
- **The kernel fails to boot:** Should the kernel fail to boot or recognise devices, the user can access the FreeBSD boot loader to choose the kernel they wish to boot.
- **Kernel works, `ps` does not:** To rectify this issue, users can recompile and install a word built with the same version of the source tree as that of the kernel.

Conclusion

In an operating system, the kernel is indicative of the highest degree of privilege in a modern general purpose system. Users trying to get themselves acquainted with a FreeBSD environment are thus advised to be aware of both the inherent nuances of the kernel as well as the troubles generally associated with it in order to build a custom kernel without running into any noticeable problems. **d**
