

Binary compatibility is essential to run your program code on various hardware, software, and operating systems. It is an old idea to make your code compatible to run on a general-purpose computer without a need to change it. But it is easier said than done. A compiled program means being compatible with multiple hardware and Application Programming Interfaces (APIs), and their corresponding Application Binary Interfaces (ABIs) need to be compatible with each other. But for now, we will be focusing only on the OS compatibility between Linux and Unix binaries and how you can make your Linux code compatible using FreeBSD.

Prerequisites and what you will learn

As mentioned, this chapter will focus on using FreeBSD to develop binary compatible Linux programs. Hence, it is evident that FreeBSD provides binary compatibility with Linux, allowing you to run Linux binaries on FreeBSD without the need for modification. Most Linux binaries run seamlessly or even better on FreeBSD, while some Linux-specific features don't. The only prerequisite here is to know how to install third-party software in Linux.

Making Linux code binary compatible.
