

vide the same services. The only difference is that FreeBSD binaries have FreeBSD glue functions and Linux binaries have Linux glue functions, which helps to link to the respective kernel statistically.

As the Linux kernel is present in the FreeBSD kernel, it might seem like an emulation. However, technically, it is way different from emulation. The first thing is that there is already a Linux kernel present in the FreeBSD kernel. Hence, the FreeBSD system will not have to emulate the entire hardware to run Linux binaries. This will allow you to make Linux binaries compatible with FreeBSD without consuming your system resources and slowing it down.

By making your Linux program binary compatible, you can run it on the FreeBSD system and other OSes too. In this chapter, we have seen how to make Linux binaries compatible with UNIX. In the next chapter, we will learn how to make it compatible with Windows using the WINE software we talked about at the beginning of this chapter. WINE again is not a way of emulating the Windows environment on FreeBSD to run Windows apps. You will learn more about it in the next chapter.
