

and associated applications. You can then grant them permissions through the `su` command to allow them to act like you. Hence, each user will be able to install WINE and use the central prefix and associated applications.

Conclusion

WINE is one of the best programs to get your Windows applications to run on FreeBSD and other operating systems. While this chapter briefs you about the basic knowledge of installing and using WINE on FreeBSD to run Windows apps, you can refer to WINE's official website for more detailed information specifically about the program. There are also some alternatives to WINE, such as dual-booting, virtual machines, and remote access. Like WINE, these three programs will also let you build Windows environments in FreeBSD and run applications.

Dual-booting allows you to run Windows apps by existing FreeBSD. So basically you can only run a single OS at a time. Virtual machines can simulate the entire hardware set of the guest OS so that you can run any applications compatible with it on the host OS. However, running VMs can consume a huge amount of system resources, making it slow. FreeBSD can also allow you to access Windows systems through remote access. As you can see although there are multiple ways of getting Windows apps to run on FreeBSD, WINE is probably the best option to choose for most use cases. **d**
