

Introduction

Among the most significant powers that you can be given as a part of a Discord server is to become its moderator. As the moderator of a Discord server, you have the capability not just to govern your own actions from a higher platform but also to determine what other members of the server can and cannot do. Being a moderator, especially on a server in which the number of members is significant, hence comes with a great amount of responsibility.

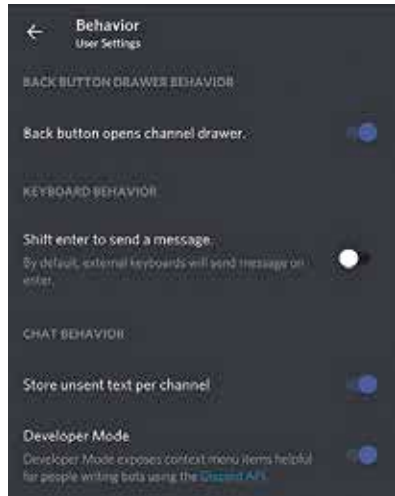

Discord allows for the assignment of roles and permissions to individual members and groups of members on a server. These permissions govern everything from banning users and preventing them from posting to changing nicknames. This customisability has several benefits to administrators in terms of keeping the discussion of a server within self-determined constraints.

This chapter shall cover the roles and permissions that you can set for the users of a Discord server as a moderator or administrator. It takes you through the steps required to implement these permissions and the technical considerations of doing so. This chapter primarily deals with setting permissions and roles on the desktop version of Discord. The steps for the mobile version are similar in nature, though with a significantly different user interface.

Turn on Developer Mode

The first step toward managing roles and responsibilities on Discord is to turn on developer mode. Developer mode allows you to copy IDs for server, channel, and user. This makes moderation a significantly easier process, allows you to deal with Discord bots, and helps you report relevant issues to Discord.

To turn on developer mode, first, go to User Settings. Here, click on the appearance tab. Here, you will see a toggle switch that allows you to turn developer mode on or off.
