

Data and Methods

When a Vue instance is generated, it adds to Vue's reactivity framework all of the properties contained in its data object. As the values of those properties change, the view “reacts,” adjusting to reflect the new values. The view will be re-rendered if this data improves. It should be remembered that data properties are only reactive if they were present when the instance was formed.

It should be remembered that these proxied properties are the only ones that are reactive. If you add a new property to an instance after it has been developed, no view changes will be triggered. Vue instances expose various valuable instance properties and methods in addition to data properties. To distinguish them from proxied data objects, these properties and methods are prefixed with \$.

You may have found that the Vue components look a lot like Custom Elements, which are part of the Web Components Spec. This is since Vue's component syntax is loosely based on the spec. Vue modules, for example, incorporate the Slot API, and are a special attribute. There are, however, a few main differences:

The Web Components Spec has been finalised, but it is not yet natively supported by all browsers. Web elements are natively supported by Safari 10.1+, Chrome 54+, and Firefox 63+. Vue modules, on the other hand, do not need any polyfills and run consistently across all compatible browsers (IE9 and above). Vue components can also be bundled within a native custom product if necessary.
