

- `// ... and vice-versa`
- `data.a = 3`
- `vm.a // => 3`

The root Vue instance, or Vue instance for short, is at the core of any Vue program, large or small. Invoking the Vue constructor, `new Vue` creates a root Vue case `()`. The constructor bootstraps our framework by compiling an HTML blueprint for it, implementing some instance data, and generating the data and event dependencies that make it immersive. `new Vue` (`/* options go here */`) accepts a single JavaScript object known as the options object. It is our responsibility to populate the object with all the Vue constructors required to bootstrap our program. But for now, we will concentrate on a single alternative, the `el` option.

Vue uses the `'el'` alternative to designate a DOM feature where our application will be mounted. Vue can find the corresponding DOM feature in our HTML and use it as the app's command prompt.

Vue.js employs an HTML-based template syntax that allows you to connect the transformed DOM to the underlying Vue instance's data declaratively. Both Vue.js templates are real HTML that can be interpreted by browsers and HTML parsers that support the spec.

Vue compiles the models into Virtual DOM render functions behind the scenes. When combined with the reactivity system, Vue can intelligently determine the smallest number of components to re-render and the smallest amount of DOM manipulations to add when the app state changes.

Explanation of Vue instance Lifecycle Hooks

The following is a list of all the incidents and hooks that a Vue instance goes through. Vue has eight life-cycle methods/events or hooks.

Js Instance Life-cycle:

- **Created hook**- The `created ()` hook is used to execute code after the instance has been created. It allows you to view reactive details, but the mounting or rendering of templates and virtual DOM has not yet been done. Even though models have not yet been installed or made, events are active, and access to reactive data is allowed in this hook.
- **Mounted hook**- The `mounted ()` hook is the most common case or hook. This hook gives you complete control over the reactive part, models, and made DOM. You have complete control over the reactive component, models, and rendered DOM in this hook.
- **Before create hook**- The first occurrence or hook that happens during
