

the construction process is the `Create ()` hook. It allows developers to execute activities until the component is to be added to the DOM. We are unable to do anything about the DOM in this case. The data in this hook and the incidents that happened during the component life-cycle are not reactive.

- **Updated hook**- The `updated ()` hook is called after the data on the component changes and the DOM re-renders. It is the safest way to complete this action if you want to reach the DOM after a property update.
- **Destroyed hook**- The `destroyed ()` hook is the last stage in the Vue.js Instance life-cycle and is used to do any final clean up.
- **Before mount hook**- The `before Mount ()` hook is called only before the original render and after the prototype or change functions that have accumulated. It is called after Vue has compiled the blueprint and modified the virtual DOM. This is a seldom-used occurrence, and in most situations, it is unnecessary to use it.
- **Before update hook**- The `before Update ()` hook is called only before the component's data shifts and the upgrade period begins. It is executed immediately before the DOM is changed and updated.
- **Before destroy hook**- The `before Destroy ()` hook is called only before the instance is destroyed. This is the second last step in the Vue Instance life-cycle and is the appropriate place to tidy up incidents or reactive subscriptions if necessary.

Explanation of Vue instance Lifecycle Hooks
