

As mentioned above, each Vue instance must go through a set of initialization steps. When you generate an instance, it must configure data observation, compile the prototype, install the instance to the DOM, and update the DOM as data changes.

Vue.js dynamic components and Vue.js computed properties.

A dynamic component is one whose position in the program is not determined at build time. It is not specified in any Vue.js template. Instead, at runtime, the dynamic component is instantiated and added to the program. A dynamic component in Vue.js is generated with the tags `<component></component>` and bound with a property. Let's look at a scenario to help you understand.

Vue.js dynamic components and Vue.js computed properties.

Computed properties are used in Vue.js when dealing with complex logic and operations. Computed properties are like processes, although there are certain variations.

In previous examples, we successfully used in-template expressions. While they are very useful, in-template expressions are still used for basic operations. If you must use a lot of abstract logic in your models, they will become bloated and difficult to manage.

When we type in the textbox, the feature returns the same value regardless of whether the property's first name or last name changes. As a result, we don't have to do something special with computation, such as remem-
