

ference. First, in the method, you need to call **count()** instead of computed, if you have a **count()** method. The main difference between the computed properties and the methods is that computed properties are cached.

```

• <script>
• export default {
•   data() {
•     return {
•       items: [1, 2, 3]
•     }
•   },
•   methods: {
•     count: function() {
•       return 'The count is ' + this.items.length * 10
•     }
•   }
• }
• </script>

```

The result of the count is internally cached. It will be cached until the data **items** property changes.

It should be noted that computed properties are updated only when reactive source updates. Regular Javascript methods are not reactive. Hence, one of the common examples to use is with **Date.now()**

Methods	Computed Properties
Functions that are meant to be called	Intended to compute existing data
Can have parameters passed in	Shouldn't have parameters passed in
Re-evaluated every time they're called	Cached based on their dependencies
Not meant to be a property	Should be used as a property
