

Angular and ReactJS. As a result, it is well-known for its simple-to-use and tidy coding.

Vue.js has style linking, which enables dynamic style changes. In any HTML tag, you can add a variable to the style attribute and have the style shift as the binding variable changes. We'll look at how to use style binding and change the formatting of variables in vue.js.

## Classes: Static and Dynamic

In Vue, modules can include both static and dynamic classes.

Static classes are those that never shift and are still present on the component. On the other side, dynamic classes are those that enable one to add and delete items as our program changes.

If we were to include a static class, we would do it exactly like we would in standard HTML:

```
<template>
  <span class="description">
    This is how you add static classes in Vue.
  </span>
</template>
```

Including static class

Dynamic classes are very close to static classes, but we must use Vue's unique property syntax, v-bind, to associate a Javascript expression with our class:

```
<template>
  <span v-bind:class="'description'">
    This is how you add static classes in Vue.
  </span>
</template>
```

JavaScript expression for v-bind

You'll find that we had to use additional quotes around the name of our complex class.

This is because the v-bind syntax accepts whatever Javascript value we transfer. By using the quotations, you ensure that Vue treats it as a string.

Additionally, Vue has a shortcut syntax for **v-bind**:
