

Or

- `const result = expression`
- `? ifTrue`
- `: ifFalse;`

ifTrue is returned if expression evaluates to real. If we don't, we'll get **ifFalse**.

Their biggest advantage is that they are brief and count as a single sentence. This allows us to include them inside our models.

Ternaries come in handy when we need to choose between two separate values inside the template:

```
<template>
  <span
    class="description"
    :class="darkMode ? 'dark-theme' : 'light-theme'"
  >
    This is how you add dynamic classes in Vue.
  </span>
</template>
```

Ternaries

If **darkMode** is set to **real**, we use the class name **dark-theme**. Otherwise, we go for a **light-theme**.

Computed Properties

The reasoning required to determine which class name to use may be a little more difficult at times.

In these circumstances, it doesn't really work within the template, so you'll want to place it in a computed prop:

```
<template>
  <span :class="computedClass">
    We've learned so much about conditional class bindings!
  </span>
</template>
```
