

frameworks, provides easy development options to the developers. Going ahead, we will learn about why one should use Vue for their web UI development projects, conditional rendering and some other information about the Vue framework.

Conditional Rendering

As far as a dynamic web application is concerned, conditional rendering is an inseparable part. With the help of conditional rendering, it becomes easy to toggle a particular element in the DOM. The process of toggling works on certain conditions given by the developer.

As Vue.js is an ahead of time framework for building user interfaces, the libraries focus on the view layer only. With conditional rendering, it becomes easy to go through the blocks, implement user-defined conditions and integrate with other functions. As a result, powerful single-page applications are created that are blended with modern tooling and supporting libraries.

Vue.js provides several ways of conditional rendering. Developers can use them according to the purpose of the software and their own needs.

The primary directives of conditional rendering are as follows:

- **v-show**
- **v-if**
- **v-else**
- **v-else if**

In this article, there will be a detailed description of what these directives mean and which directive can be used for what motive, along with descriptive examples.

v-if

The directive **v-if** is commonly used to render a particular block. But this type of conditional rendering is only possible if the expressions of the directive return a true value. This means **v-if** will neither hide the element nor render anything until the system passes the value or the given expression becomes true.

For example,

- `<!-- This div is conditionally rendering -->`
- `<div v-if="isBool">`
- `<p>This is a paragraph</p>`
- `</div>`
