

similar to that of **v-if**. The syntax of **v-show** can be understood with the help of the following example,

- `<p v-show="isBool">This paragraph is not hidden</p>`
- `<p v-show="!isBool">This paragraph is hidden</p>`

The difference between **v-if** and **v-show** is that the elements used inside the **v-show** directive are always going to remain and rendered in the DOM. **v-show** only does the job of toggling the **display** CSS property of the element. But, it can neither be executed along with the **<template>** element, unlike above mentioned conditional rendering directives, nor it is compatible to work with **v-else**.

The reason why developers use **v-show** is its simplicity. The elements get rendered regardless of what the initial toggling has to offer. **v-show** runs on CSS-based toggling. The initial rendering costs for the same are a bit on the higher side.

If the developer needs to toggle the blocks regularly, **v-show** is the preferable directive of all. But on the other hand, if the conditions of the block are unlikely to change for a long duration during the runtime, **v-if** will prove more efficient in terms of cost and usage.

Why Developers Should Choose Vue.js For Web UI Development

There are many UI development frameworks out there then why Vue use them?
