

List Rendering

Dynamic list rendering to provide a collection of equally grouped items

List rendering is a technique often used in front-end web creation. The consumer is often presented with a set of equally grouped data in a succinct and comfortable format using dynamic list rendering. We will see collections of content in various places on almost any web application we use. We've grown used to having a list of trends, posts, potential supporters, etc., on the dashboard. The material reflected in these lists is determined by a variety of variables, including our Twitter feed, who we follow, and our likes. Hence, we should state categorically that all this data is dynamic. Let's learn how to use the **v-for** directive in Vue to build dynamic lists. We'll also go into the details of whether the main attribute should be included in this situation.

Lists

Lists generate a windowed list (row) of objects, with users seeing just the visible rows (e.g., **FixedSizeList**, **VariableSizeList**). Lists render rows using a **Grid** (internally), relaying props to the inner grid.
