

Grid

The **grid** creates virtualized tabular data around the vertical and horizontal axis (e.g., **FizedSizeGrid**, **VariableSizeGid**). It just renders the grid cells necessary to fill themselves depending on the horizontal/vertical scroll positions currently in use.

How Does Virtualization of Lists Work?

“Virtualizing” a list of items entails holding a window and repositioning it within the set. Windowing in react-virtualized works is accomplished by the following:

- Taking a minimal container DOM element with relative positioning (e.g., **ul>**) (window).
- Using a large DOM element to facilitate scrolling.
- The child components are positioned inside the jar, with their top, left, distance, and height styles set.

Rather than rendering thousands of objects from a list concurrently
